

Life Cycles

Flesch-Kincaid: 4.7 | Words: 151

Living things are born, they grow, they change, and they reproduce. To reproduce means to make more of a living thing of the same kind. When new living things are born, they are called offspring. Offspring or babies sometimes look like their parents. Some are born looking very different from their parents. Baby animals grow. They change or mature. Animals begin to look different. They change and grow bigger and stronger. When they are fully-grown the animal is now an adult. It reproduces. It cares for its young. Adults grow old and die. The young start the process again after they grow into adults. This is the cycle of life. Every animal has a different life cycle. We must work to make sure animal life cycles are not interrupted by humans. We must not disturb these important life cycles if we want to continue to have amazing animals on planet earth.
